

**ANALYSIS OF SAMPLES COLLECTED AT SPECIAL-STUDY SITES
NEW GARDEN TOWNSHIP, CHESTER COUNTY, SPRAY IRRIGATION PROJECT**

Traditionally, wastewater has been treated and discharged to streams. However, a rapidly growing suburban population in southeastern Pennsylvania is generating an increasing quantity of wastewater. Discharge to streams often degrades stream-water quality. A government-wide move is underway to limit the quantity of nutrients discharged to streams. In addition, many streams are being designated as high or exceptional value streams. An alternative to stream discharge is land application of treated effluent. An increasing number of communities in Pennsylvania are implementing land-treatment systems to dispose of treated sewage effluent. Disposal of treated effluent by spraying onto the land surface recharges the ground-water system and provides an extra purifying step in the wastewater treatment process and does not directly degrade stream-water quality.

The USGS, in cooperation with the Chester County Water Resources Authority and the Pennsylvania Department of Environmental Protection (PaDEP), is currently conducting a study on the effects of treated sewage effluent sprayed on the land surface in New Garden Township, Chester County, Pennsylvania. New Garden Township is not contributing funding to the study, but is graciously allowing the use of their spray-irrigation site as a study site. The New Garden Township site lies west of Kennett Square Borough just north of Baltimore Pike (fig. 11). The site covers approximately 58 acres. The PaDEP issued a permit for a maximum application rate of 300,000 gallons of effluent per day. Application began in May of 1999.

The objectives of this study are to determine the percentage of applied effluent that recharges the ground-water system and the percentage that is lost to evapotranspiration using a monthly water-budget approach, to characterize the effect of land treatment on ground-water and surface-water quality, and to determine the fate and transport of nitrogen as it moves from effluent into soil, soil water, ground water, crops and the atmosphere by determining and quantifying a nitrogen budget.

The site has been intensively instrumented in order to reach project objectives. The USGS has drilled 6 shallow (CH5173, CH5175, CH5177, CH5179, CH5180, and CH5181) and 4 bedrock wells (CH5172, CH5174, CH5176, and CH5178) at the New Garden Township site to monitor ground-water quality and ground-water-level fluctuations within the spray application area. A deep (CH5182) and shallow (CH5183) well pair act as control wells outside the application area. Data for water year 2000 for these wells are presented in this report on pages 548-587. A system of suction lysimeters was installed at three locations in the application area with additional lysimeters installed as control lysimeters outside the application area (fig. 11). Lysimeters were installed at depths ranging from 3 to 15 feet. Lysimeter data are presented in this report, pages 413-428.

A surface-water flow-measuring station (01479678) has been installed on the stream located downgradient in respect to ground-water-flow directions to measure the quantity of streamflow leaving the approximately 45 acre site (0.07 mi^2). A stilling well has been installed in a pond (station 01479677) downgradient of the spray fields to measure pond level fluctuations. A flume (station 01479676) was installed at the lowest elevation point of the field site above the pond. A swale directs overland flow from part of the study site (0.03 mi^2) through the flume and stage is recorded electronically. Data for these surface-water sites can be found on pages 323-337.

Ground-water and surface-water sampling on a monthly basis are used to characterize changes in ground-water and surface-water quality. Storm samples are also collected using an automatic sampler at the flume station 01479676. Treated sewage effluent and precipitation are sampled on a monthly basis to quantify nutrient inputs to the site.

Other data collected electronically at the site include precipitation amounts, numerous other meteorological parameters such as wind speed and wind direction, soil moisture, and applied effluent. Soil and plant samples are collected in the application field and in control areas in order to determine the mass of nitrogen in the soil-plant system.

System design engineers and regulators are in need of data on monthly and seasonal variations in recharge and evapotranspiration for use in designing and managing spray irrigation systems. Quantifying monthly evapotranspiration rates will provide additional field data to assist regulators in permitting new spray irrigation systems. Results from the monthly water budgets could potentially change the present regulations regarding application rates. For water managers, the monthly water budgets could provide a ground-water recharge percentage for issuances of water-use credits. Assessments of nutrient loading to ground water and surface water would quantify the percentage of nutrients applied to the land surface that enters and moves through the ground-water system to the surface-water system.

For additional information, contact Curtis Schreffler at the U.S. Geological Survey, 111 Great Valley Parkway, Malvern, PA 19355; 610-647-9008 ext 220 (email clschref@usgs.gov).

REMARKS--Some values for dissolved nitrate-nitrogen exceed values for dissolved nitrogen. These results are within the limits of analytical precision and methods.
